| Question 7 (4 poin | ts): Name any | two methods used for pa | arameter passing | between a process | and the kernel. | |
| (a) | | | (b) | | | |
| | | | | | | |

Question 8 (5 points): Tell the output of the following code. Assume that the parent process running following code has the PID = 100. Each new fork() creates a new process. Each child process gets the process ID in following way. The first digits of the child process ID are all borrowed from the parent. The last digit is equal to the number of fork() done by the parent. For example, if parent whose PID = 100, the child created in result of the first fork will have the PID = 1001 and the child created in result of the second fork will have PID = 1002.

Assume that each instruction runs in the order. Meaning instructions written on smaller line numbers will necessarily execute before the instructions written on bigger line numbers.

Hint:The function getpid() returns the PID of the calling process.

```
1
             # include <stdio.h>
2
             int main(void)
3
             {
4
             int pid=0;
             pid = fork();
5
6
             if ( pid == 0)
7
                      printf("%d,", getpid());
8
9
                      pid = fork();
10
                      if ( pid == 0)
11
                               printf("%d,", getpid());
12
                               pid = fork();
13
                               if ( pid > 0)
14
15
                                         printf("%d,", getpid());
16
17
                                         pid = fork();
18
                                         if (pid > 0)
19
                                         {
                                                  printf("%d,", getpid());
pid = fork();
20
21
22
                                                  if ( pid == 0)
23
                                                  {
24
                                                           printf("%d,", getpid());
25
                                                  }
26
                                        }
27
                               }
                      }
28
29
30
             }
             else if (pid > 0)
31
32
             {
                      printf("%d,", getpid());
33
34
             }
35
             return 0;
36
             }
```

| Question 9 (5 points): Inspired from the "100,1001,1002,1003" (without the quotes) Meaning the line written before will execute | he above code, write a similar code using fork() which prints the string.). You can make the same assumption about the execution order as above e before. |

Question 10 (10 points): Suppose in a machine the CPU executes one instruction per clock cycle. There are three Ethernet cards in the machine. Each machine runs some CPU cycle then reads data from any of the Ethernet cards. The processes arrive in order, i.e. P_1 then P_2 and then P_3

Explanation: The columns CPU Burst+Length show the number of CPU clock cycles needed by the process. The columns I/O Burst+Length show the number of Ethernet cycles needed after each CPU Burst. The table only shows the order in which processes need those cycles, how they will execute depends upon the scheduling algorithm.

- Using the FCFS algorithm list down the order of execution of the processes.
- Calculate the total time of execution of all processes.
- Calculate the average waiting time.

| Process Name | Length | CPU Burst | I/O Burst |
|----------------|--------|-----------|-----------|
| P_1 | 3 | Yes | - |
| P_2 | 6 | Yes | - |
| P_3 | 8 | Yes | - |
| P_1 | 12 | - | Yes |
| P_2 | 4 | - | Yes |
| P_3 | 7 | - | Yes |
| P_1 | 7 | Yes | - |
| P_2 | 5 | Yes | - |
| P ₃ | 3 | Yes | - |
| P_1 | 13 | - | Yes |
| P_2 | 10 | - | Yes |
| P ₃ | 7 | - | Yes |
| P_1 | 3 | Yes | - |
| P_2 | 25 | Yes | - |
| P ₃ | 12 | Yes | - |
| P_1 | 17 | - | Yes |
| P_2 | 15 | - | Yes |
| P ₃ | 8 | - | Yes |
| P_1 | 3 | Yes | - |
| P_2 | 3 | Yes | - |
| P ₃ | 3 | Yes | - |
